Agile Methods for Software Development

22 March 2024

1. Identify your pair programming partner.

Pair Programming Partner: Bhagawat Chapagain

2. Identify the user story/task you implemented alone.

Individual User Story/Task: Design user interface for the app

3. Describe your experience working alone on the user story. How long did it take to implement and test the story?

Working alone allowed me to have complete control over the development process, from planning to implementation and testing. I could work at my own pace, which was both an advantage and a disadvantage depending on my motivation and focus. This alone would take around two hours.

4. Describe your experience working with a pair programming partner on the user story. How long did it take to implement and test the story?

Pair programming involved constant communication and collaboration with my partner. It required us to discuss our ideas, agree on a plan, and jointly write and test the code. However,

this proved to be effective as it provided an extra set of eyes, allowing us to create solutions to problems sooner. Not only that, we were also able to provide knowledge to each other in case one was struggling. Although this story is arguably more challenging than the individual one, it took around three hours, but it definitely would take far more time.

5. Describe the advantages and disadvantages for you and your teammate while pair programming. What worked well? What didn't work well?

Pair programming offers a unique set of advantages and disadvantages that can impact the development process. One of the key benefits is the immediate feedback and error checking provided by having two developers work on the same code, which in our case leads to higher quality code. Additionally, pair programming encourages knowledge sharing and learning, as each partner brings their own strengths and expertise to the table. This collaborative approach also tends to improve team communication and collaboration skills, which are invaluable in a team-oriented environment. However, pair programming does come with some challenges. Conflicts can come up if there is a mismatch in working styles or skill levels between the partners, which can lead to frustration and inefficiency. Pair programming also requires good communication skills, which can be challenging for some individuals, but luckily was not the case for us. In my opinion, having two sets of eyes on the code helped catch bugs early, and brainstorming solutions together often led to more innovative approaches. However, differences in coding styles and preferences sometimes led to issues in the overall project.

6. Would you recommend pair programming? Why or why not?

I would recommend pair programming, especially for the intricate or critical parts of the project. It enhances code quality, encourages learning, and can be more efficient in the long run.

7. Will you use pair programming on future user stories? Why or why not?

I would use pair programming on future user stories where collaboration can significantly add value, such as in designing algorithms or debugging tricky issues. However, for simpler tasks, I might prefer working alone to maintain a faster pace.
