Our application is designed to give users opportunities to share their video game lists while also discovering new games that may suit their tastes. Users can find games on our application which will use the RAWG video game database. Users will be recommended games based on their preferences. In addition users will be able to search up games using filters. Users can add ratings and comments to individual games. They will also be able to add games to lists that show their ratings and comments on all the games in the list. If a user decides to, lists can be published on a forum board on our web application. This allows other users to leave a rating and comment on users' lists.

Course Technologies

Redis - Used for caching recently accessed data

React - This will be used for front-end framework

Next.js - This will be used for back-end framework

Typescript - Used for development in Javascript

Additional Technologies

Docker- Platform to build, run, and share containerized applications. Used to ensure working code across different platforms as well as to deploy and scale the application.

RAWG API- Video game database api that contains comprehensive data about many video games. It will be used to query information about video games that will be served to users.

AWS (Amazon Web Services)- AWS will be used to ensure high availability, scalability, and security for the application. Using AWS will allow us to reliably deploy our application in a cost-effective manner, ensuring optimal performance even with a large number of users.
